Abstract By introducing a new perturbation strategy, a perturbed feasible sequential quadratically constrained quadratic programming (SQCQP) algorithm is proposed. The algorithm is globally and superlinearly convergent, and the uniformly positive definiteness assumption in the global convergence analysis of traditional SQCQP algorithms is removed.

Key words SQCQP, perturbation strategy, uniformly positive definiteness, global convergence, superlinear convergence

摘要: 通过引入新的摄动策略,提出一个摄动的可行序列二次约束二次规划 (SQCQP)算法 .该算法全局和超线性收敛并且去掉了传统 SQCQP算法全局收敛性分析中的一致正定性假设 .

Consider the inequality constrained nonlinear programming problem:

$$\min_{x \in R^n} f_0(x)$$

s. t. $f_i(x) \leq 0$, $i \in I \xrightarrow{\text{def}} \{1, 2, \dots, m\}$, (1) where $f_i, i \in \{0\} \cup I$: $R^n \to R$ are smooth functions. Denote the feasible set for problem (1) by $F = \{x \in R^n: f_i(x) \leq 0, i \in I\}$.

During the past several decades, the researches of sequential quadratic programming (SQP) methods for solving problem (1) have been greatly improved, but when the problems to be solved are highly nonlinear, SQP methods usually show slow convergence, or even fail. For this, in recent years a so-called sequential quadratically constrained quadratic programming (SQCQP) method has been proposed proposed I have a square and proposed I have a square and square and under weaker conditions, the global, superlinear, and quasi-quadratic convergence are obtained. Compared with SQP methods, at each iteration SQCQP methods only need to solve a

quadratically constrained quadratic programming (QCQP) subproblem, and without any correctional directions the Maratos effect will not occur and therefore the superlinear convergence can be obtained. QCQP subproblem is a quadratic approximation of the original problem, so it is a better approximation than the quadratic programming (QP) subproblem solved in SQP methods, therefore the expected numerical performance of SQCQP may be better than SQP.

Generally, in the global convergence analysis, the positive definiteness or even uniformly positive definiteness of the (approximate) Hessian matrix Go of the objective function f_0 is needed to be assumed, which is considered as a strong assumption. In order to overcome this shortcoming, Liu^[5] presented a perturbed QCQP subproblem by adding a positive multiple of identity matrix to Go. By suitably adjusting the perturbation parameters, the algorithm in Reference [5] (belongs to penalty function type SQCQP algorithms) is proved to be globally convergent only under the assumption that G_0 is positive semidefinite. Motivated by the perturbation idea in Reference [5], we propose a new perturbation strategy (which is simpler than that given in Reference [5]) to modify the feasible SQCQP algorithm in

Reference [1]. By using the newly proposed strategy to update the perturbation parameters, we remove the assumption of uniformly positive definiteness used in the global convergence analysis of the algorithm in Reference [1]. The new algorithm is also proved to be globally and superlinearly convergent.

Algorithm

We begin this section by making the following basic hypothesis.

Assumption 1 The functions f_i , $i \in \{0\} \cup I$, are first-order continuously differentiable.

For simplicity, we denote the gradient vectors $\nabla f_i(x)$ by $g_i(x), i \in \{0\} \cup I$. For the current feasible iterate $x^k \in F$, we consider the QCQP subproblem as follows, which is perturbed from that in Reference [1].

$$\min_{\substack{(z,d) \in \mathbb{R}^{n+1} \\ \text{s. t. } g_{0}(x^{k})^{T} d \leqslant V_{0} z,}} V_{0} z + \frac{1}{2} d^{T} (G_{0}^{k} + ME) d$$
s. t. $g_{0}(x^{k})^{T} d \leqslant V_{0} z,$

$$f_{i}(x^{k}) + g_{i}(x^{k})^{T} d + \frac{1}{2} d^{T} G_{0}^{k} d \leqslant V_{i}^{e} z, i \in I,$$

$$\frac{1}{2} e_{k} ||d||^{2} \leqslant c^{e_{k}^{(2k+1)}}, \qquad (2)$$

where M and G are positive parameters, E is an $n \times n$ identity matrix, $V_i(i \in \{0\} \cup I), c, f$ are positive constants, and G^k ($i \in \{0\} \cup I$) are symmetric, positive semidefinite matrices. The QCQP subproblem (2) is convex and therefore can be cast as a second-order cone program and then be solved efficiently by using interior point algorithms^[6].

We call (z_k, d^k) a KKT (Karush-Kuhn-Tucker) point for subproblem (2) if there exist multipliers k, $v_k \in R, u^k = (u_i^k, i \in I) \in R^m \text{ such that}$

$$(G_0^k + ME) d^k + {}_{-k}g_0(x^k) + \sum_{i \in I} u_i^k (g_i(x^k) +$$

$$G^{k}d^{k}) + {}^{Q_{k}}v^{k}d^{k} = 0,$$

$$V_{0} = V_{0_{k}} + \sum_{i=1}^{k} u_{i}^{k}V_{i}^{Q_{k}},$$

$$(3)$$

$$V_0 = V_{0_k} + \sum_{k \in I} \iota_k^k V_i^{e_k},$$
 (4)

$$0 \leqslant _{-k} \perp (V_{0Zk} - g_0(x^k)^T d^k) \geqslant 0, \qquad (5)$$

$$0 \leqslant u_k^k \perp (V_i^k z_k - f_i(x^k) - g_i(x^k)^T d^k - g$$

$$\frac{1}{2} \left(d^k \right)^T G_i^k d^k \geqslant 0, i \in I, \tag{6}$$

$$0 \leqslant v_k \perp (c^{e_k^{(2^{\frac{\epsilon}{4}-1)}}} - \frac{1}{2} e_k^{\epsilon} ||d^{\epsilon}||^2) \geqslant 0, \qquad (7)$$

where notation $x \perp y$ means $x^T y = 0$.

The following lemmas show that the OCOP subproblem (2) is well defined, and their proofs are similar to those in Reference [1] due to the fact that $G_0^k + ME$ is a positive definite matrix.

Suppose that Assumption 1 holds. Then (i) QCQP subproblem (2) has an optimal solution, (ii) (z_k, d^k) is an optimal solution of subproblem (2) if and only if it is a KKT point for subproblem (2).

Lemma 2 Suppose that Assumption 1 holds, and that (z_k, d^k) is an optimal solution of subproblem (2).

Then (i)
$$z \leqslant -\frac{1}{2V_0} (d^k)^T (\dot{G} + ME) \dot{d} \leqslant -$$

 $\frac{1}{2V_0}M|d^k|^2$, (ii) $z_k = \bigoplus d^k = \bigoplus x^k$ is a Fritz John point for problem (1), (iii) if $z_k < 0$, then d^k is a feasible descent direction of problem (1) at x^k .

Now we present the perturbed feasible SQCQP algorithm as follows.

Algorithm A

Step 0 Initialization. Choose $V_i > 0, i \in \{0\} \cup I$, $M > 0, e_0 > 0, f > 1, c > 0, T \in (0, 0.5), U, Z, \theta \in (0, 0.5)$ 1), $x^0 \in F$, $G^0(i \in \{0\} \cup I)$ symmetric and positive semidefinite. Set k = 0.

Step 1: Solve QCQP. Solve subproblem (2) to obtain a KKT point (z_k, d^k) . If k = 0, set $d = ||d^k||$. If

Step 2 Line search. Compute the step size λ_k , the first value of λ in the sequence $\{1, U, U^{\dagger}, \dots\}$ that

$$f_0(x^k + \lambda d^k) \leqslant f_0(x^k) + \operatorname{Tr} g_0(x^k)^T d^k, \qquad (8)$$

$$f_i(x^k + \lambda d^k) \leqslant 0, i \in I. \qquad (9)$$

Step 3 Generate perturbation parameter. If $\frac{||d^k||}{d}$ $\leq Z_{\text{set}}M_{1} = \theta M_{\text{and}} d = \|d^*\|_{1} + \text{otherwise set}M_{1} =$ M

Step 4 Update. Set $x^{k+1} := x^k + \lambda_k d^k$. Compute new symmetric positive semidefinite matrices G^{-1} ($i \in$ $\{0\} \bigcup I$) as well as positive parameters f_{k+1} . Set k:=k+ 1 and go to step 1.

Remark From Lemma 2(iii), we know that the line search in step 2 can be terminated in a finite number of computations, and therefore Algorithm A is well-defined. The updating strategy of perturbation parameters in step 3 is new and different from (more precisely, simpler than) that in Reference [5].

Global and superlinear convergence

We first establish the global convergence of the proposed algorithm without assuming that G_0^k is (uniformly) positive definite. Once Algorithm A stops finitely at x^k , it follows from Lemma 2 that x^k is a Fritz John point for problem (1). Now assume that an

infinite sequence $\{x^k\}$ of iterates is generated by Algorithm A, we will show that there exists an accumulation point x^* of $\{x^k\}$ such that it is a KKT point for problem (1).

Assumption 2 (i) The sequences $\{x^k\}$ and $\{G^k\}$, i $\in \{0\} \cup I$ are bounded. (ii) The parameter sequence $\{e_k\}$ is strictly positive and bounded.

Define the index set of shrinking the perturbation parameters by $S = \{k M_1 = \theta M\}$.

Lemma 3 Suppose that Assumptions 1 and 2 hold. Then the sequences $\{k\}$, $\{d^k\}$ and $\{z_k\}$ are bounded.

Proof The boundedness of $\{k\}$ is obvious from formula (4). From the last constraint of subproblem (2), it follows that $\{d^k\}$ is bounded. This together with the boundedness of $\{x^k\}$ and the inequality: $0 \ge z_k \ge$ $\frac{1}{V_0}g_0(x^k)^T d^k \ge -\frac{1}{V_0}||g_0(x^k)|| \cdot ||d^k|| \text{ shows that } \{z_k\} \text{ is}$ bounded.

Suppose that Assumptions 1 and 2 hold. Then there exists an infinite index set K such that $\lim_{k \to \infty} d^k = 0$.

Proof We divide the proof into two cases. Case 1 S is an infinite set. From step 3 of Algorithm A and $Z \in (0,1)$, it is obvious that there exists an index set K such that $\lim_{k \to \infty} d^k = 0$.

Case 2 S is a finite set. From step 3 of Algorithm A, we know that there exists a constant \overline{M} 0 such that Mor all k. Without loss of generality, suppose by contradiction that there exists a constant $\overline{k} > 0$ such that

$$||d^{k}|| \geqslant k$$
, for all k . (10)

This together with the last constraint of subproblem (2) shows that

$$0 < e_{\inf} = \inf \{e_k\} \leqslant e_k, \text{ for all } k.$$
 (11)

Next we will prove that there is a constant $\overline{\lambda}$ > 0 such that the step $\operatorname{size} \lambda \geqslant \lambda^{-}$ for all k.

Analyze inequality (8). From Taylor expansion, formula (5), Lemma 2(i) and formula (10), we have $f_0(x^k + \lambda d^k) - f_0(x^k) - \mathcal{T}_{Q_0}(x^k)^T d^k = (1 - \lambda d^k)^T d^k$ $\text{T} \lambda g_0(x^k)^T d^k + o(\lambda) \leqslant (1 - \text{T}) \lambda \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{2} (1 + \text{T}) \delta \text{V}_{0Zk} + o(\lambda) \leqslant -\frac{1}{$

 $- T_{\lambda} M |d^{k}|^{2} + o(\lambda) \leqslant - \frac{1}{2} \overline{M} (1 - T_{\lambda}) k^{2} \lambda + o(\lambda).$

This shows that inequality (8) holds for all k and $\lambda > 0$ small enough.

Analyze inequalities (9). From Taylor expansion, formula (6), Lemma 2(i), formula (10) and formula 广西科学 2009年 5月 第 16卷第 2期

(11), we have for $i \in I$,

$$f_{i}(x^{k} + \lambda d^{k}) = f_{i}(x^{k}) + \lambda g_{i}(x^{k})^{T} d^{k} + o(\lambda) \leq (1 - \lambda) f_{i}(x^{k}) + \lambda V_{i}^{e_{k}} z_{k} - \frac{1}{2} \lambda (d^{k})^{T} d^{k} + o(\lambda) \leq -\frac{1}{2V_{0}} \lambda V_{i}^{e_{k}} M |d^{k}|^{2} + o(\lambda) \leq -\frac{1}{2V_{0}} V_{i}^{e_{\inf}} \overline{M} k^{2} \lambda + o(\lambda).$$

This together with $\frac{1}{2V_0}V_i \stackrel{e}{=}_{inf} \overline{Mk}^2 > 0$ show that the inequalities (9) hold for all k and $\lambda > 0$ small enough.

Summarizing the analysis above, we can conclude that there exists $a\lambda > 0$ such that $\lambda \geqslant \lambda$ hold for all k. So from inequality (8), formula (5), Lemma 2(i) and formula (10), we have

$$f_0(x^{k+1}) \leqslant f_0(x^k) + \mathbb{T}_k g_0(x^k)^T d^k \leqslant f_0(x^k) + \mathbb{T}_k V_0 z_k \leqslant f_0(x^k) - \frac{1}{2} \mathbb{T}_k M |d^k|^2 \leqslant f_0(x^k) - \frac{1}{2} \mathbb{T}_k M^2,$$
 for all k . Thus the sequence $\{f_0(x^k)\}$ is decreasing. Since $\{x^k\}$ is bounded, there exist an infinite set K_1 and a point x^* such that $\lim_{k \in K_1} x^k = x^*$, and therefore $\lim_{k \in K_1} f_0(x^k) = f_0(x^k)$. So we have $\lim_{k \to \infty} f_0(x^k) = f_0(x^k)$. This contradicts formula (12), and the proof is completed.

Corollary 1 Suppose that Assumptions 1 and 2 hold. Then $\lim_{n \to \infty} M = 0$.

Lemma 5 Suppose that Assumptions 1 and 2 hold. If $\lim_{k \to \infty} d^k = 0$, then $\lim_{k \to \infty} z_k = 0$.

Proof From formula (5) and Lemma 2(i), we have $g_0(x^k)^T d^k N \leqslant z_k \leqslant 0$, for all k. This together with $\lim_{k \to \infty} d^k = 0$ and the boundedness of $\{x^k\}$ shows that $\lim_{z \to 0}.$

In order to obtain the global convergence, we further make the following assumptions.

Suppose that the Mangasarian-Assumption 3 From ovitz constraint qualification holds at each limit point x^* of $\{x^k\}$, i. e., there exists a vector $d \in R^n$ such that $g_i(x^*)^T d < 0, \forall i \in I(x^*) \stackrel{\text{def}}{=} \{i \in I, f_i(x^*) = i \in I, f_i(x^*) = i \in I, f_i(x^*) \}$ 0}.

Assumption 4 The multiplier sequence $\{v_k\}$ is bounded.

Theorem 1 Suppose that Assumptions 1~ 4 hold. Then Algorithm A either stops finitely at a Fritz John point x^k for problem (1) or generates an infinite sequence $\{x^k\}$ of iterates such that there exists an accumulation point x^* which is a KKT point for problem (1).

From Lemma 4, Lemma 5 and the Proof boundedness of $\{x^k\}$, we have that there exist an

index set K and a point x^* such that $(x^k, d^k, z_k) \rightarrow (x^*, 0, 0), k \in K$. So following the proof of Theorem 3. 2 in Reference [1], we can conclude that x^* is a KKT point for problem (1).

Assumption 5 (i) f_i , $i \in \{0\} \cup I$, are the third-order continuously differentiable. (ii) The matrices G_i , $i \in \{0\} \cup I$, are chosen as $G_i = \nabla^2 f_i(x^k)$, $i \in \{0\} \cup I$, if i is sufficiently large, and the parameter sequence $\{G_i^k\}$ satisfies $\lim_{k \to \infty} G_k^k = 0$. (iii) The sequence $\{G_i^k\}$ of matrices is uniformly positive definite, i. e., there exist two positive constants i and i such that i is i that i is i in i in i is i in i in

Using Corollary 1, similar to Theorem 4. 2 in Reference [1], we can prove the following result.

Theorem 2 Suppose that Assumptions $2 \sim 5$ hold. Then Algorithm A is superlinearly convergent, i. e., $||x^{k-1} - x^*|| = o(||x^k - x^*||)$.

4 Conclusion

In this paper, a nonmonotone line search has been proposed for guaranteeing the global convergence of WYL conjugate gradient method. It needs to estimate the Lipschitz constant but the estimation is easy and available in practical. In particular, if m=0, then the new nonmonotone line search will reduce to a monotone line search and the WYL conjugate gradient method with the monotone line search has also global convergence. The Numerical experiments show that

WYL method with the nonmonotone line search is available and efficient in practical computation-
